

## Gauss-Newton method

- ▶ nonlinear least-squares
- ▶ Gauss-Newton method

## Nonlinear least-squares

**nonlinear least-squares (NLLS) problem:** find  $x \in \mathbb{R}^n$  that minimizes

$$\|r(x)\|^2 = \sum_{i=1}^m r_i(x)^2,$$

where  $r : \mathbb{R}^n \rightarrow \mathbb{R}^m$

- ▶  $r(x)$  is a vector of 'residuals'
- ▶ reduces to (linear) least-squares if  $r(x) = Ax - y$

## Position estimation from ranges

estimate position  $x \in \mathbb{R}^2$  from approximate distances to beacons at locations  $b_1, \dots, b_m \in \mathbb{R}^2$  *without* linearizing

- ▶ we measure  $\rho_i = \|x - b_i\| + v_i$   
( $v_i$  is range error, unknown but assumed small)
- ▶ NLLS estimate: choose  $\hat{x}$  to minimize

$$\sum_{i=1}^m r_i(x)^2 = \sum_{i=1}^m (\rho_i - \|x - b_i\|)^2$$

## Gauss-Newton method for NLLS

**NLLS:** find  $x \in \mathbb{R}^n$  that minimizes  $\|r(x)\|^2 = \sum_{i=1}^m r_i(x)^2$ , where  $r : \mathbb{R}^n \rightarrow \mathbb{R}^m$

- ▶ in general, very hard to solve exactly
- ▶ many good heuristics to compute *locally optimal* solution

### Gauss-Newton method:

given starting guess for  $x$

repeat

    linearize  $r$  near current guess

    new guess is linear LS solution, using linearized  $r$

until convergence

## Gauss-Newton method, more detail

- ▶ linearize  $r$  near current iterate  $x^{(k)}$ :

$$r(x) \approx r(x^{(k)}) + Dr(x^{(k)})(x - x^{(k)})$$

where  $Dr$  is the Jacobian:  $(Dr)_{ij} = \partial r_i / \partial x_j$

- ▶ write linearized approximation as

$$\begin{aligned} r(x^{(k)}) + Dr(x^{(k)})(x - x^{(k)}) &= A^{(k)}x - b^{(k)} \\ A^{(k)} &= Dr(x^{(k)}), \quad b^{(k)} = Dr(x^{(k)})x^{(k)} - r(x^{(k)}) \end{aligned}$$

- ▶ at  $k$ th iteration, we approximate NLLS problem by linear LS problem:

$$\|r(x)\|^2 \approx \|A^{(k)}x - b^{(k)}\|^2$$

- ▶ next iterate solves this linearized LS problem:

$$x^{(k+1)} = (A^{(k)T}A^{(k)})^{-1} A^{(k)T}b^{(k)}$$

- ▶ repeat until convergence (which *isn't* guaranteed)

## Gauss-Newton example

- ▶ 10 beacons
- ▶ + true position  $(-3.6, 3.2)$ ;  $\diamond$  initial guess  $(1.2, -1.2)$
- ▶ range estimates accurate to  $\pm 0.5$

## Example

NLLS objective  $\|r(x)\|^2$  versus  $x$ :

- ▶ for a linear LS problem, objective would be nice quadratic 'bowl'
- ▶ bumps in objective due to strong nonlinearity of  $r$

## Convergence

objective of Gauss-Newton iterates:

- ▶  $x^{(k)}$  converges to (in this case, global) minimum of  $\|r(x)\|^2$
- ▶ convergence takes only five or so steps
- ▶ final estimate is  $\hat{x} = (-3.3, 3.3)$
- ▶ estimation error is  $\|\hat{x} - x\| = 0.31$ , (smaller than range accuracy!)

# Convergence

convergence of Gauss-Newton iterates:

## Regularized Gauss-Newton

useful variation on Gauss-Newton: add regularization term

$$\|A^{(k)}x - b^{(k)}\|^2 + \mu\|x - x^{(k)}\|^2$$

so that next iterate is not too far from previous one (hence, linearized model still pretty accurate)
